School of Information Science and Technology SIST

ShanghaiTech University

Slides based on UC Berkley's CS61C

New-School Machine Structures

Software   **Hardware**

- **Parallel Requests**
  Assigned to computer
  e.g., Search "cats"

- **Parallel Threads**
  Assigned to core
  e.g., Lookup, Ads

- **Parallel Instructions**
  >1 instruction @ one time
  e.g., 5 pipelined instructions

- **Parallel Data**
  >1 data item @ one time
  e.g., Deep Learning for image classification
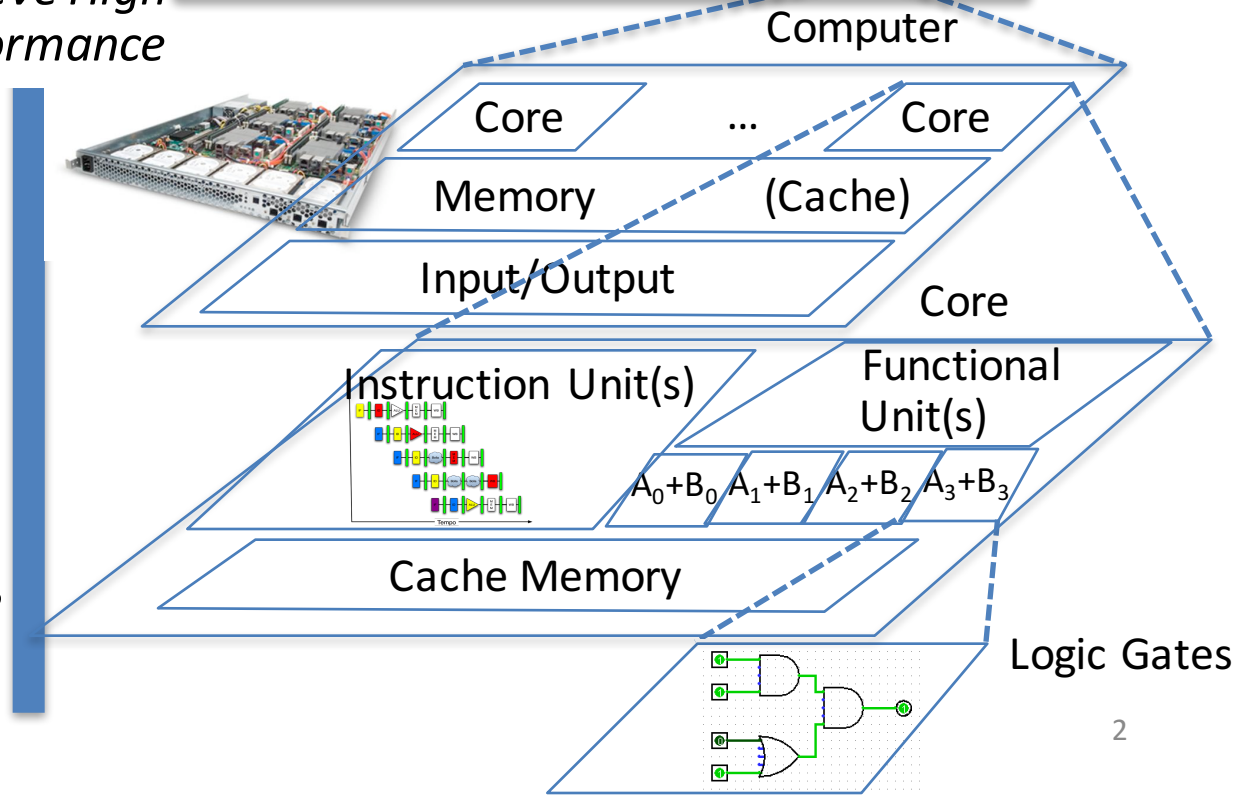

- **Hardware descriptions**
  All gates @ one time

- **Programming Languages**

Harness Parallelism & Achieve High Performance

2011

Urs Hoelzle, Google SVP

- Google disclosed that it continuously uses enough electricity to power 200,000 homes, but it says that in doing so, it also makes the planet greener.

- Average energy use per typical user per month is same as running a 60-watt bulb for 3 hours (180 watt-hours).

http://www.nytimes.com/2011/09/09/technology/google-details-and-defends-its-use-of-electricity.html
Google's WSCs

Ex: In Oregon

# Containers in WSCs

Inside WSC

Inside Container

Server, Rack, Array

Google Server Internals

Warehouse-Scale Computers

- Datacenter
  - Collection of 10,000 to 100,000 servers
  - Networks connecting them together
- ***Single gigantic*** machine
- Very large applications (Internet service): search, email, video sharing, social networking
- Very high availability
- "…WSCs are no less worthy of the expertise of computer systems architects than any other class of machines" Barroso and Hoelzle, 2009

Unique to WSCs

- Ample Parallelism
  - **Request-level Parallelism:** ex: Web search
  - **Data-level Parallelism:** ex: Image classifier training
- Scale and its Opportunities/Problems
  - **Scale of economy**: low per-unit cost
  - Cloud computing: rent computing power with low costs (ex: AWS)
  - **High # of failures**

    ex: 4 disks/server, annual failure rate: 4%
    $\rightarrow$ WSC of 50,000 servers: 1 disk fail/hour
- Operation Cost Count
  - Longer life time (>10 years)
  - **Cost of equipment purchases << cost of ownership**

WSC Architecture
1U Server:

8 cores,

16 GB DRAM,

4x1 TB disk

Rack:
40-80 severs,

Local Ethernet (1-10Gbps) switch

(30$/1Gbps/server)

Array (aka cluster):

16-32 racks

Expensive switch

(10X bandwidth → 100x cost)

WSC Storage Hierarchy

Lower latency to DRAM in another server than local disk
Higher bandwidth to local disk than to DRAM in another server

1U Server:
DRAM: 16GB, 100ns, 20GB/s
Disk: 2TB,   10ms,   200MB/s

Rack(80 severs):
DRAM: 1TB,   300us,   100MB/s
Disk: 160TB, 11ms,   100MB/s

Array(30 racks):
DRAM: 30TB,   500us, 10MB/s
Disk: 4.80PB, 12ms, 10MB/s

Workload Variation

- Online service: Peak usage 2X off-peak

Impact on WSC software

- ***Latency, bandwidth*** → Performance
  - Independent data set within an array
  - Locality of access within server or rack
- ***High failure rate*** → Reliability, Availability
  - Preventing failures is expensive
  - Cope with failures gracefully
- ***Varying workloads*** → Availability
  - Scale up and down gracefully
- More challenging than software for single computers!

Power Usage Effectiveness

- Energy efficiency
  - Primary concern in the design of WSC
  - Important component of the total cost of ownership

- Power Usage Effectiveness (PUE):

$$\frac{\textbf{Total Building Power}}{\textbf{IT equipment Power}}$$

  - A power efficiency measure for WSC
  - Not considering efficiency of servers, networking
  - Perfection = 1.0
  - Google WSC's PUE = 1.2
PUE in the Wild (2007)

**FIGURE 5.1:** LBNL survey of the power usage efficiency of 24 datacenters, 2007 (Greenberg et al.)

Where Data Center Power Goes

Load Profile of WSCs

- Average CPU utilization of 5,000 Google servers, 6 month period
- Servers rarely idle or fully utilized, operating most of the time at **10% to 50%** of their maximum utilization

Energy-Proportional Computing: Design Goal of WSC

- Energy = Power x Time, Efficiency = Computation / Energy
- Desire:
    - Consume almost no power when idle ("Doing nothing well")
    - Gradually consume more power as the activity level increases
Cause of Poor Energy Proportionality
- CPU: 50% at peek, 30% at idle
- DRAM, disks, networking: 70% at idle!
- Need to improve the energy efficiency of peripherals

Cloud Computing: Scale of Economy

Instance	Per Hour	Ratio to small	Compute Units	Virtual Cores	Compute Unit / Core	Memory (GiB)	Disk (GiB)	Address
Standard Small	$0.065	1.0	1.0	1	1.00	1.7	160	32bit
Standard Large	$0.260	4.0	4.0	2	2.00	7.5	850	64bit
Standard Extra Large	$0.520	8.0	8.0	4	2.00	15.0	1680	64bit
High-Memory Extra Large	$0.460	5.9	6.5	2	3.25	17.1	420	64bit
High-Memory Double Extra Large	$0.920	11.8	13.0	4	3.25	34.2	850	64bit
High-Memory Quadruple Extra Large	$1.840	23.5	26.0	8	3.25	68.4	1680	64bit
High-CPU Medium	$0.165	2.0	5.0	2	2.50	1.7	350	32bit
High-CPU Extra Large	$0.660	8.0	20.0	8	2.50	7.0	1680	64bit

- March 2014 AWS Instances & Prices
- Closest computer in WSC example is Standard Extra
- At these low rates, Amazon EC2 can make money!
  - even if used only 50% of time
- Virtual Machine(VM) plays an important role

Agenda

- Warehouse Scale Computing

- Request-level Parallelism

  e.g. Web search

- Data-level Parallelism

  – Hadoop, Spark

  – MapReduce

- (Bonus) Convolutional Neural Networks

Request-Level Parallelism (RLP)

- Hundreds of thousands of requests per sec.
  - Popular Internet services like web search, social networking, …
  - Such requests are largely independent
    - Often involve read-mostly databases
    - Rarely involve read-write sharing or synchronization across requests
- Computation easily partitioned across different requests and even within a request

Anatomy of a Web Search (1/3)

- Google "cats"
    - Direct request to "closest" Google WSC
    - Front-end load balancer directs request to one of many arrays (cluster of servers) within WSC
    - Within array, select one of many Goggle Web Servers (GWS) to handle the request and compose the response pages
    - GWS communicates with Index Servers to find documents that contains the search word, "cats"
    - Return document list with associated relevance score

Anatomy of a Web Search (2/3)

- In parallel,
  - Ad system: run ad auction for bidders on search terms
- Use docids (Document IDs) to access indexed documents
- Compose the page
  - Result document extracts (with keyword in context) ordered by relevance score
  - Sponsored links (along the top) and advertisements (along the sides)

Anatomy of a Web Search (3/3)

- Implementation strategy

  - Randomly distribute the entries

  - Make many copies of data (a.k.a. "replicas")

  - Load balance requests across replicas

- **Redundant copies** of indices and documents

  - Breaks up search hot spots, e.g. "Taylor Swift"

  - Increases opportunities for **request-level parallelism**

  - Makes the system more **tolerant of failures**

Clicker/Peer Instruction: Which Statement is True

- **A: Idle servers consume almost no power.**

- **B: Disks will fail once in 20 years, so failure is not a problem of WSC.**

- **C: The search requests of the same keyword from different users are dependent.**

- **D: More than half of the power of WSCs goes into cooling.**

- **E: WSCs contain many copies of data.**

Agenda

- Warehouse Scale Computing

- Request-level Parallelism

  e.g. Web search

- Data-level Parallelism

  - MapReduce

  - Hadoop, Spark

- (Bonus) Convolutional Neural Networks

Data-Level Parallelism (DLP)

- SIMD

  – Supports data-level parallelism in a single machine

  – Additional instructions & hardware

  e.g. Matrix multiplication in memory

- DLP on WSC

  – Supports data-level parallelism across multiple machines

  – MapReduce & scalable file systems

What is MapReduce?

- Simple data-parallel **programming model** and **implementation** for processing large dataset

- Users specify the computation in terms of
  - a **map** function, and
  - a **reduce** function

- Underlying runtime system
  - Automatically **parallelize** the computation across large scale clusters of machines.
  - **Handles** machine **failure**
  - **Schedule** inter-machine communication to make efficient use of the networks

Jeffrey Dean and Sanjay Ghemawat, "MapReduce: Simplified Data Processing on Large Clusters," *6th USENIX Symposium on Operating Systems Design and Implementation, 2004*.

What is MapReduce used for?

- At Google:
  - Index construction for Google Search
  - Article clustering for Google News
  - Statistical machine translation
  - For computing multi-layers street maps
- At Yahoo!:
  - "Web map" powering Yahoo! Search
  - Spam detection for Yahoo! Mail
- At Facebook:
  - Data mining
  - Ad optimization
  - Spam detection

Inspiration: Map & Reduce Functions, ex: Python

Calculate : $\sum_{n=1}^{4} n^2$
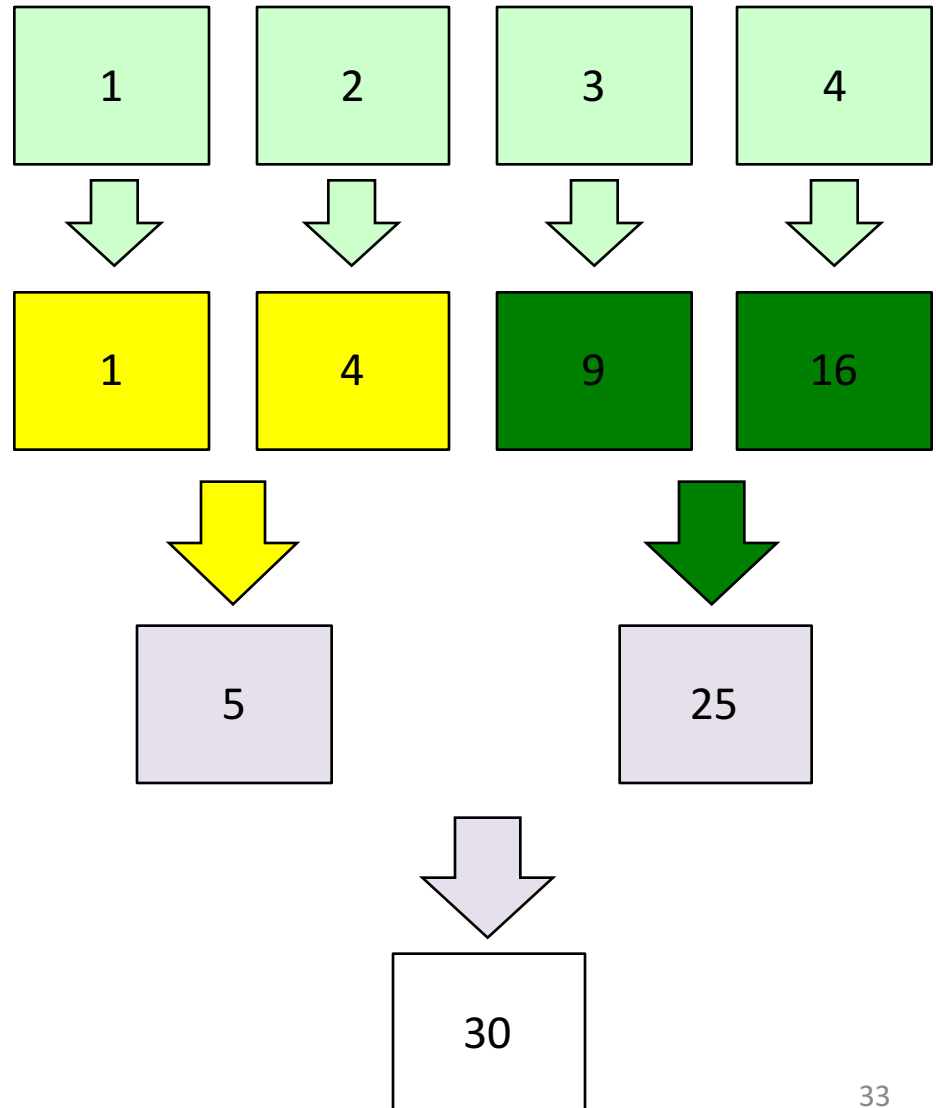

```
A = [1, 2, 3, 4]
def square(x):
    return x * x
def sum(x, y):
    return x + y
reduce(sum,
    map(square, A))
```

MapReduce Programming Model

- ***Map***: `(in_key, in_value)` → `list(interm_key, interm_val)`

```
map(in_key, in_val):
    // DO WORK HERE
    emit(interm_key,interm_val)
```

  - Slice data into "shards" or "splits" and distribute to workers
  - Compute set of intermediate key/value pairs

- ***Reduce***: `(interm_key, list(interm_value))` → `list(out_value)`

```
reduce(interm_key, list(interm_val)):
    // DO WORK HERE
    emit(out_key, out_val)
```

  - Combines all intermediate values for a particular key
  - Produces a set of merged output values (usually just one)

MapReduce Word Count Example

Task of counting the number of occurrences of each word in a large collection of documents.

User-written Map function reads the document data and parses out the words. For each word, it writes the (key, value) pair of (word, 1). That is, the word is treated as the intermediate key and the associated value of 1 means that we saw the word once.

Map phase: (doc name, doc contents) → list(word, count)

```
// "I do I learn" → [("I",1),("do",1),("I",1),("learn",1)]
map(key, value):
    for each word w in value:
        emit(w, 1)
```

MapReduce Word Count Example

***Task of counting the number of occurrences of each
word in a large collection of documents.***

The intermediate data is then sorted by MapReduce by keys and
the user's Reduce function is called for each unique key. In this
case, Reduce is called with a list of a "1" for each occurrence of
the word that was parsed from the document. The function adds
them up to generate a total word count for that word.

Reduce phase: (word, list(counts)) → (word, count_sum)
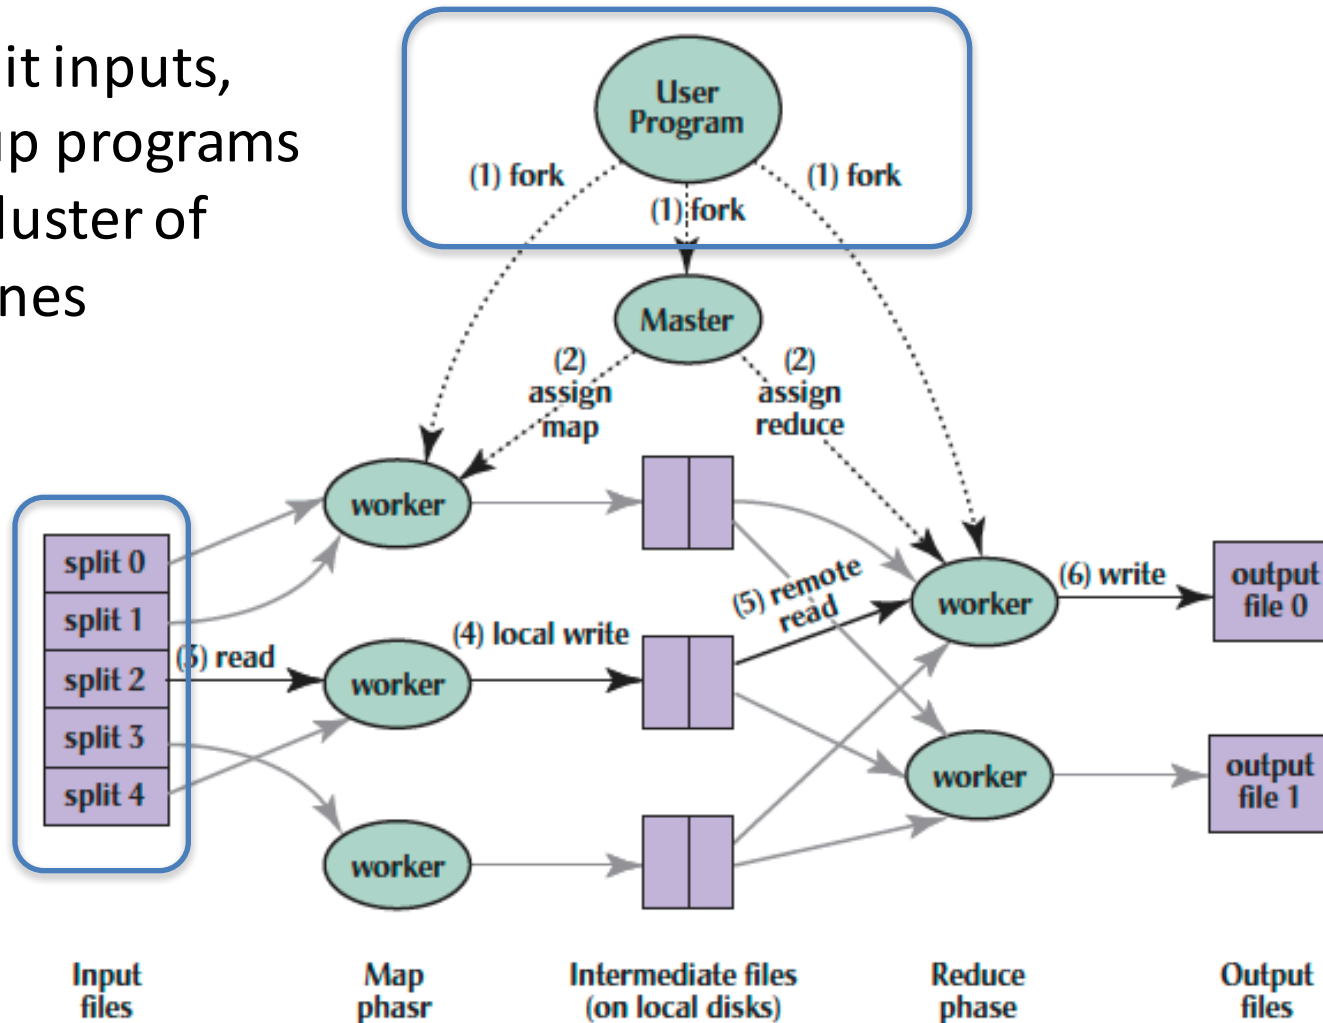

```
// ("I", [1,1]) → ("I",2)

reduce(key, values):
  result = 0
  for each v in values:
    result += v
  emit(key, result)
```
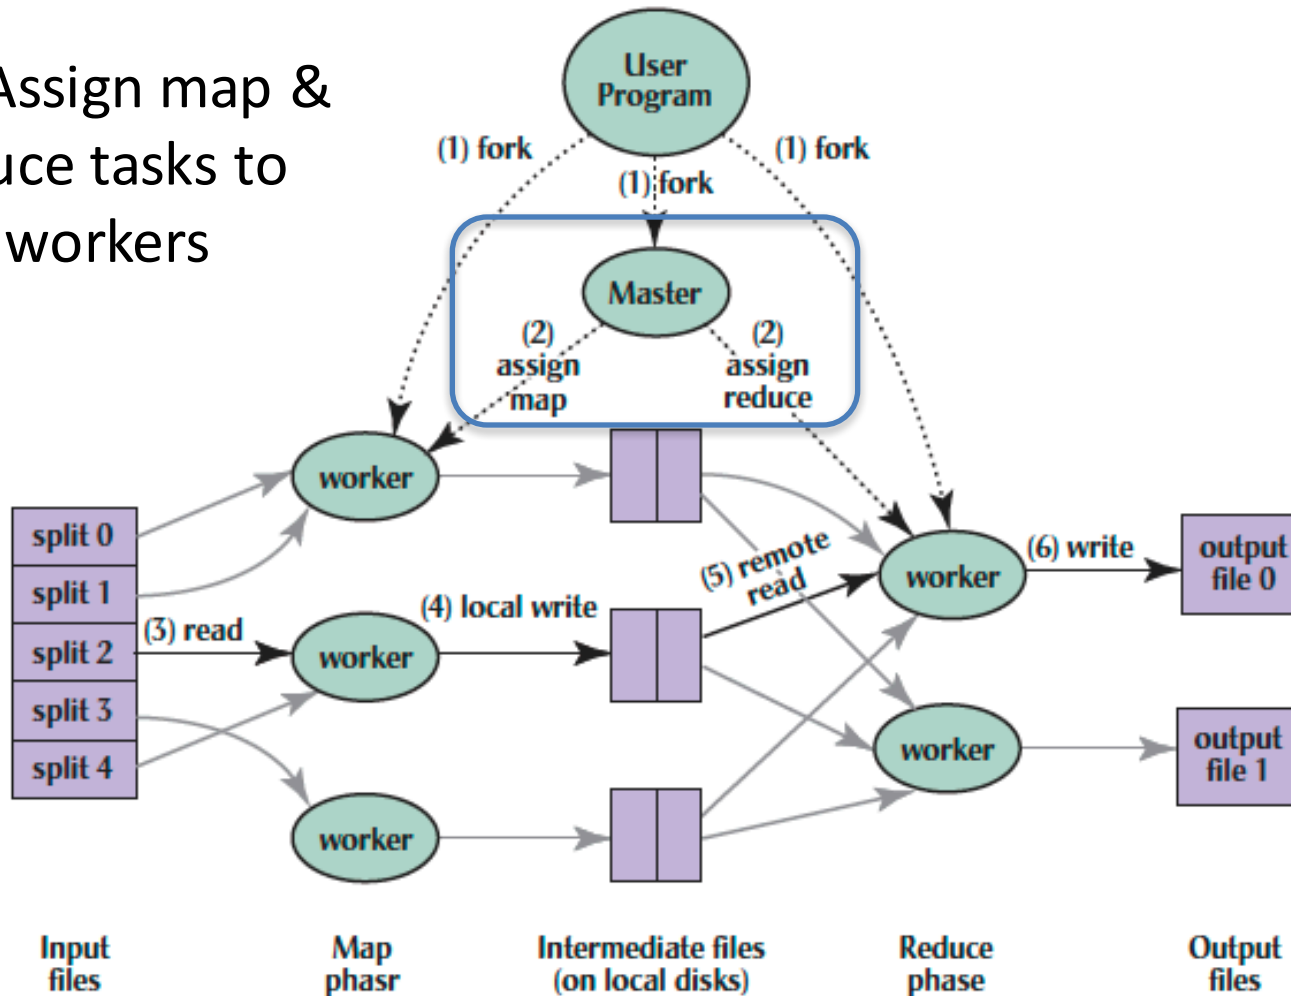

MapReduce Implementation
MapReduce Execution

(1) Split inputs, start up programs on a cluster of machines

MapReduce Execution

(2) Assign map & reduce tasks to idle workers

MapReduce Execution

(3) Perform a map task, generate intermediate key/value pairs
(4) Write to the buffers

MapReduce Execution

(5) Read intermediate key/value pairs, sort them by its key.

MapReduce Execution

(6) Perform a reduce task for each intermediate key, write the result to the output files

Big Data Framework: Hadoop & Spark

- Apache Hadoop
  - Open-source MapReduce Framework
  - Hadoop Distributed File System (HDFS)
  - Hadoop YARN Resource Management
  - MapReduce Java APIs
  - more than half of the Fortune 50 used Hadoop (2013)

- Apache Spark
  - Fast and general engine for large-scale data processing.
  - Running on HDFS
  - Provides Java, Scala, Python APIs for
    - Database
    - Machine learning
    - Graph algorithm

Summary

- Warehouse Scale Computers
  - New class of computers
  - Scalability, energy efficiency, high failure rate
- Request-level parallelism
  e.g. Web Search
- Data-level parallelism on a large dataset
  - MapReduce
  - Hadoop, Spark
