ShanghaiTech University

Slides based on UC Berkley's CS61C

New-School Machine Structures

2011

- Google disclosed that it continuously uses enough electricity to power 200,000 homes, but it says that in doing so, it also makes the planet greener.
- Average energy use per typical user per month is same as running a 60-watt bulb for 3 hours (180 watt-hours).

Urs Hoelzle, Google SVP

http://www.nytimes.com/2011/09/09/technology/google-details-and-defends-its-use-of-electricity.html

Google's WSCs

Containers in WSCsInside WSCInside Container

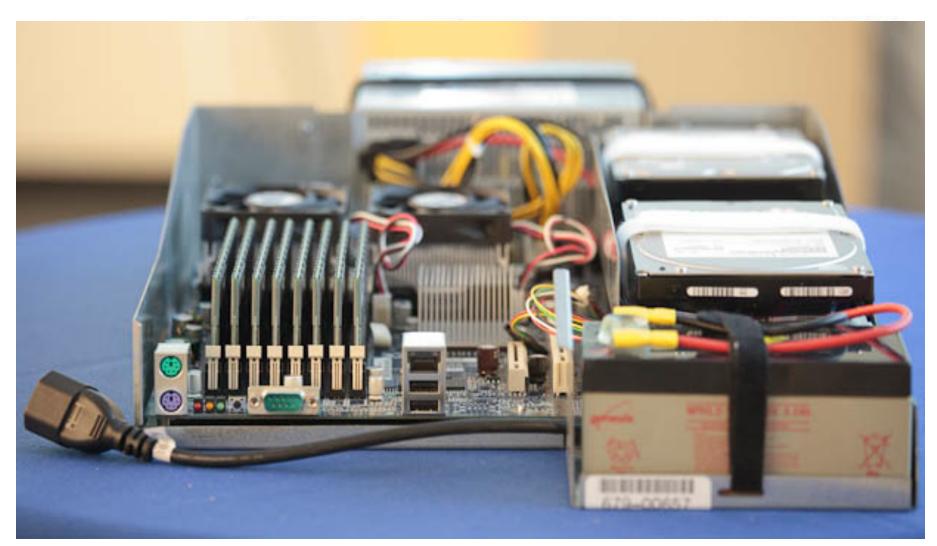

Server, Rack, Array

Google Server Internals

Open Compute Project

- Share designs of data center products
 - Facebook, Intel, Nokia, Google, Apple,
 Microsoft, Seagate Technology, Dell, Cisco,
 Goldman Sachs, Lenovo, ...
- Design and enable the delivery of the most efficient server, storage and data center hardware designs for scalable computing.
- Openly sharing ideas, specifications and other intellectual property is the key to maximizing innovation and reducing operational complexity
- All Facebook Data Centers are 100% OCP

Warehouse-Scale Computers

- Datacenter
 - Collection of 10,000 to 100,000 servers
 - Networks connecting them together
- *Single gigantic* machine
- Very large applications (Internet service): search, email, video sharing, social networking
- Very high availability
- "...WSCs are no less worthy of the expertise of computer systems architects than any other class of machines" Barroso and Hoelzle, 2009

Unique to WSCs

- Ample Parallelism
 - Request-level Parallelism: ex: Web search
 - Data-level Parallelism: ex: Image classifier training
- Scale and its Opportunities/Problems
 - Scale of economy: low per-unit cost
 - Cloud computing: rent computing power with low costs (ex: AWS)
 - High # of failures

ex: 4 disks/server, annual failure rate: 4% → WSC of 50,000 servers: 1 disk fail/hour

- Operation Cost Count
 - Longer life time (>10 years)
 - Cost of equipment purchases << cost of ownership</p>

WSC Architecture

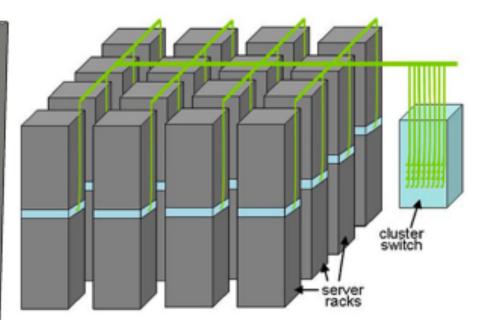

1U Server:

8 cores, 16 GB DRAM, 4x1 TB disk

Rack:

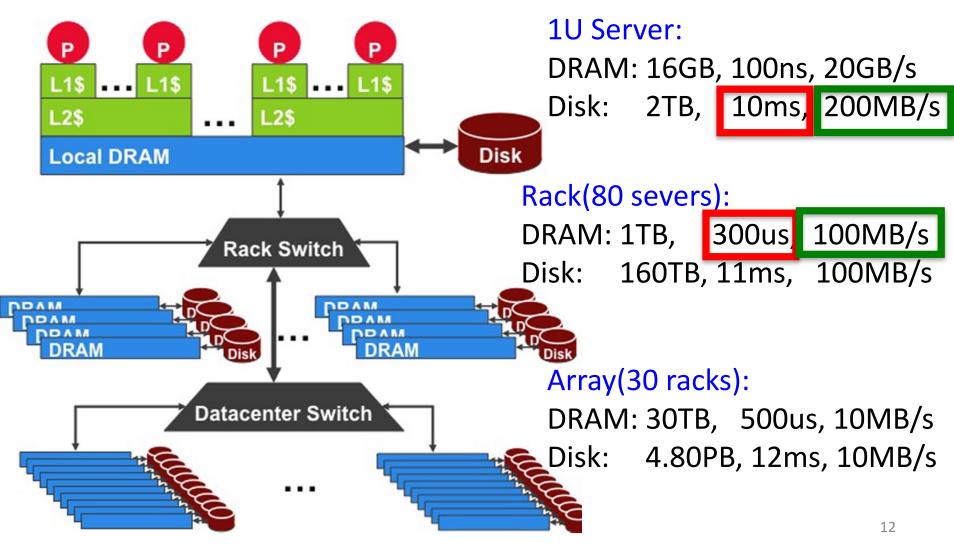

Array (aka cluster):
16-32 racks
Expensive switch
(10X bandwidth → 100x cost)

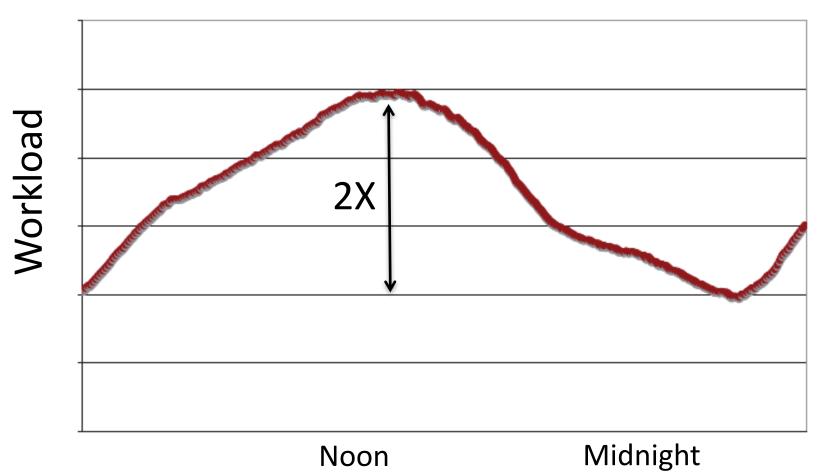

40-80 severs, Local Ethernet (1-10Gbps) switch

WSC Storage Hierarchy

Lower latency to DRAM in another server than local disk Higher bandwidth to local disk than to DRAM in another server

Workload Variation

• Online service: Peak usage 2X off-peak

Impact on WSC software

- *Latency, bandwidth* → Performance
 - Independent data set within an array
 - Locality of access within server or rack
- *High failure rate* → Reliability, Availability
 - Preventing failures is expensive
 - Cope with failures gracefully
- Varying workloads → Availability
 - Scale up and down gracefully
- More challenging than software for single computers!

Power Usage Effectiveness

- Energy efficiency
 - Primary concern in the design of WSC
 - Important component of the total cost of ownership
- Power Usage Effectiveness (PUE):

Total Building Power

IT Equipment Power

- A power efficiency measure for WSC
- Not considering efficiency of servers, networking
- Perfection = 1.0
- Google WSC's PUE = 1.2

PUE in the Wild (2007)

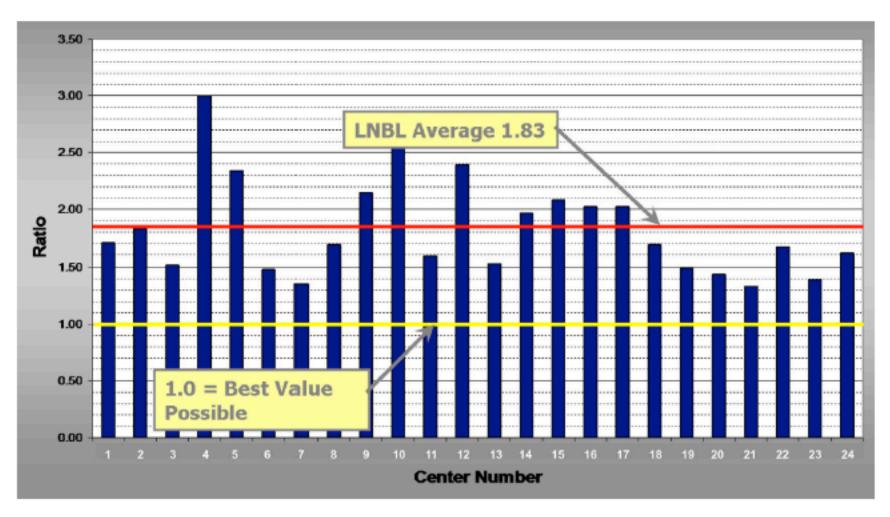

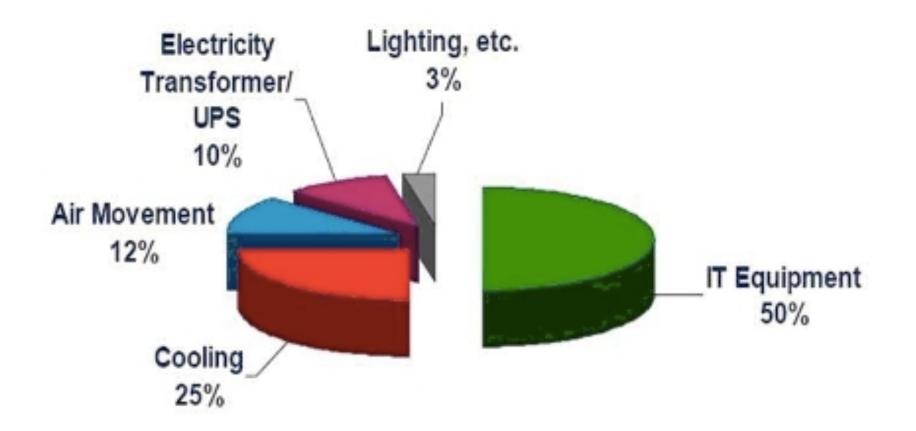

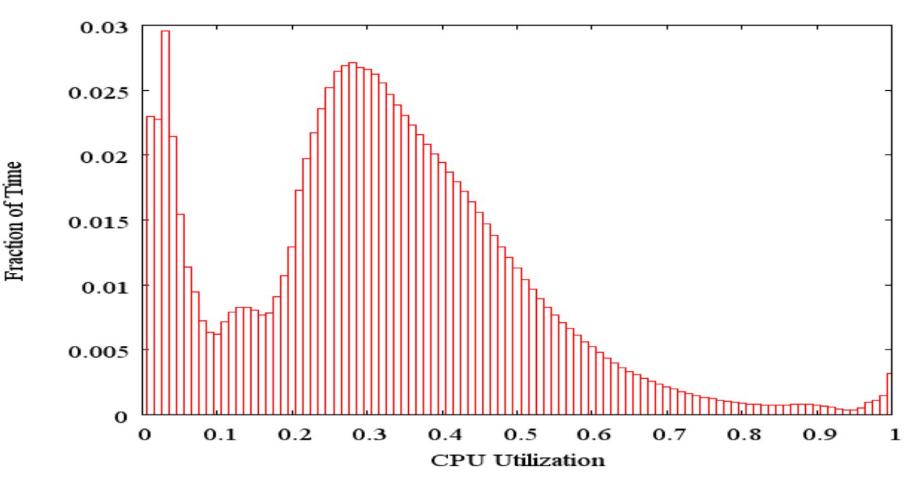

FIGURE 5.1: LBNL survey of the power usage efficiency of 24 datacenters, 2007 (Greenberg et al.)

Where Data Center Power Goes

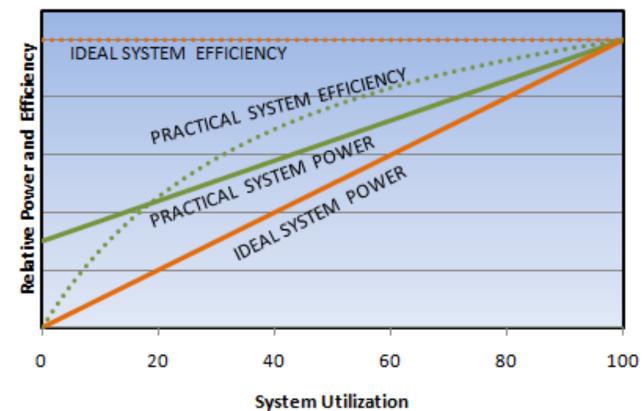

Load Profile of WSCs

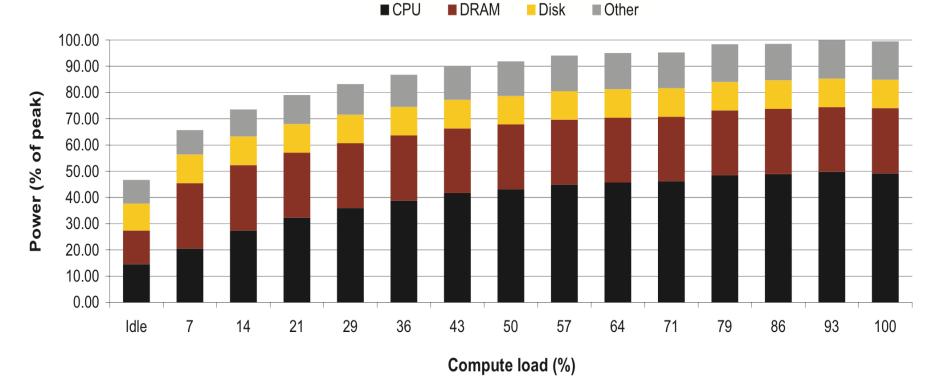

- Average CPU utilization of 5,000 Google servers, 6 month period
- Servers rarely idle or fully utilized, operating most of the time at 10% to 50% of their maximum utilization

Energy-Proportional Computing: Design Goal of WSC

- Energy = Power x Time, Efficiency = Computation / Energy
- Desire:
 - Consume almost no power when idle ("Doing nothing well")
 - Gradually consume more power as the activity level increases

Cause of Poor Energy Proportionality

- CPU: 50% at peek, 30% at idle
- DRAM, disks, networking: 70% at idle!
- Need to improve the energy efficiency of peripherals

Cloud Computing: Scale of Economy

					Network	Linux On
Name	Memory	vCPUs	Storage	Arch	Performance	Demand
M1 General Purpose Small	1.7 GB	1	160 GB	32/64-bit	Low	\$0.044 hourly
M1 General Purpose Medium	3.75 GB	1	410 GB	32/64-bit	Moderate	\$0.087 hourly
M1 General Purpose Extra						
Large	15.0 GB	4	1680 GB	64-bit	High	\$0.35 hourly
C1 High-CPU Medium	1.7 GB	2	350 GB	32/64-bit	Moderate	\$0.13 hourly
C1 High-CPU Extra Large	7.0 GB	8	1680 GB	64-bit	High	\$0.52 hourly
I2 Extra Large	30.5 GB	4	800 GB	64-bit	Moderate	\$0.853 hourly

General Purpose GPU Extra						
Large	61.0 GB	4	EBS only	64-bit	High	\$0.9 hourly
General Purpose GPU 16xlarge	732.0 GB	64	EBS only	64-bit	20 Gigabit	\$14.4 hourly
X1 Extra High-Memory 16xlarge	976.0 GB	64	1920 GB	64-bit	10 Gigabit	\$6.669 hourly

- May 2017 AWS Instances & Prices
- Closest computer in WSC example is Standard Extra
- At these low rates, Amazon EC2 can make money!
 - even if used only 50% of time
- Virtual Machine(VM) plays an important role

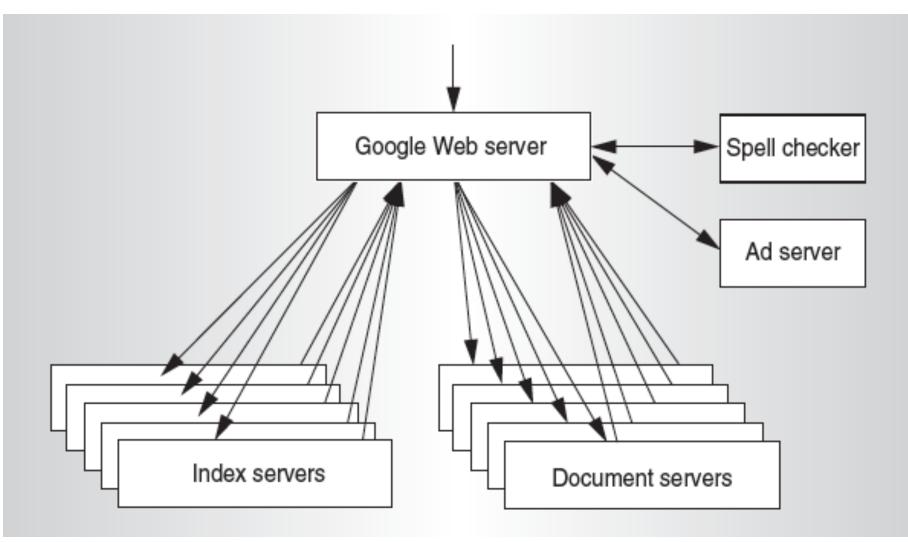

Agenda

- Warehouse Scale Computing
- Request-level Parallelism
 e.g. Web search
- Data-level Parallelism
 - Hadoop, Spark
 - MapReduce
- (Bonus) Convolutional Neural Networks

Request-Level Parallelism (RLP)

- Hundreds of thousands of requests per sec.
 - Popular Internet services like web search, social networking, ...
 - Such requests are largely independent
 - Often involve read-mostly databases
 - Rarely involve read-write sharing or synchronization across requests
- Computation easily partitioned across different requests and even within a request

Funny Cats Big Compilation 2015! [NEW] - YouTube

https://www.youtube.com/watch?v=eVo3LbVWjWc

Dec 2, 2014 - Uploaded by Funny Animals Channel New Crazy compilation of 2014. ENJOY and SUBSCRIBE, Merry Christmas!

Anatomy of a Web Search (1/3)

- Google "cats"
 - Direct request to "closest" Google WSC
 - Front-end load balancer directs request to one of many arrays (cluster of servers) within WSC
 - Within array, select one of many Goggle Web Servers (GWS) to handle the request and compose the response pages
 - GWS communicates with Index Servers to find documents that contains the search word, "cats"
 - Return document list with associated relevance score

Anatomy of a Web Search (2/3)

- In parallel,
 - Ad system: run ad auction for bidders on search terms
- Use docids (Document IDs) to access indexed documents
- Compose the page
 - Result document extracts (with keyword in context) ordered by relevance score
 - Sponsored links (along the top) and advertisements (along the sides)

Anatomy of a Web Search (3/3)

- Implementation strategy
 - Randomly distribute the entries
 - Make many copies of data (a.k.a. "replicas")
 - Load balance requests across replicas
- *Redundant copies* of indices and documents
 - Breaks up search hot spots, e.g. "Taylor Swift"
 - Increases opportunities for *request-level parallelism*
 - Makes the system more *tolerant of failures*

Question: Which Statement is True

- A: Idle servers consume almost no power.
- B: Disks will fail once in 20 years, so failure is not a problem of WSC.
- C: The search requests of the same keyword from different users are dependent.
- D: More than half of the power of WSCs goes into cooling.
- E: WSCs contain many copies of data.

Agenda

- Warehouse Scale Computing
- Request-level Parallelism e.g. Web search
- Data-level Parallelism
 - MapReduce
 - Hadoop, Spark
- (Bonus) Convolutional Neural Networks

Data-Level Parallelism (DLP)

- SIMD
 - Supports data-level parallelism in a single machine
 - Additional instructions & hardware
 - e.g. Matrix multiplication in memory
- DLP on WSC
 - Supports data-level parallelism across multiple machines
 - MapReduce & scalable file systems

Problem Statement

- How process large amounts of raw data (crawled documents, request logs, ...) every day to compute derived data (inverted indices, page popularity, ...) when computation conceptually simple but input data large and distributed across 100s to 1000s of servers so that finish in reasonable time?
- Challenge: Parallelize computation, distribute data, tolerate faults without obscuring simple computation with complex code to deal with issues

Solution: MapReduce

- Simple data-parallel *programming model* and *implementation* for processing large datasets
- Users specify the computation in terms of
 - a *map* function, and
 - a *reduce* function
- Underlying runtime system
 - Automatically *parallelize* the computation across large scale clusters of machines
 - *Handles* machine *failure*
 - Schedule inter-machine communication to make efficient use of the networks

Jeffrey Dean and Sanjay Ghemawat, "MapReduce: Simplified Data Processing on Large Clusters," 6th USENIX Symposium on Operating Systems Design and Implementation, 2004. (optional reading, linked on course homepage – a digestible CS paper at the 61C level)

What is MapReduce used for?

- At Google:
 - Index construction for Google Search
 - Article clustering for Google News
 - Statistical machine translation
 - For computing multi-layers street maps
- At Yahoo!:
 - "Web map" powering Yahoo! Search
 - Spam detection for Yahoo! Mail
- At Facebook:
 - Data mining
 - Ad optimization
 - Spam detection

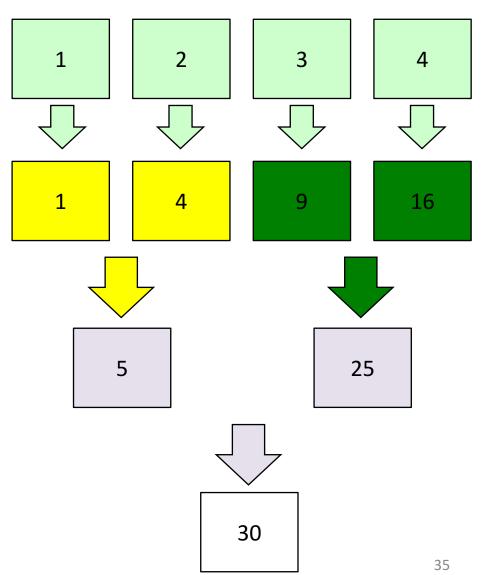

Inspiration: Map & Reduce Functions, ex: Python

Calculate : $\sum n^2$

n=1

A = [1, 2, 3, 4]def square(x): return x * x def sum(x, y): return x + y

reduce(sum, map(square, A))

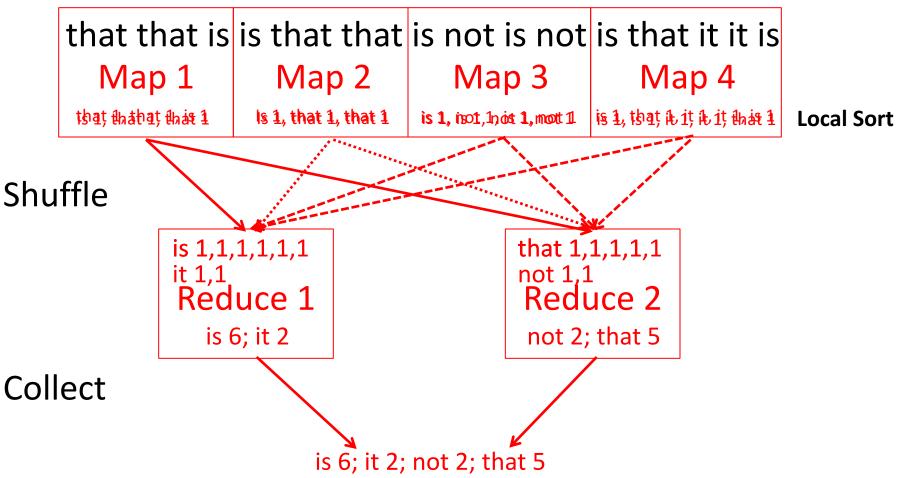

MapReduce Programming Model

- Map: (in_key, in_value) → list(interm_key, interm_val)
 map(in_key, in_val):
 // DO WORK HERE
 emit(interm_key, interm_val)
 - Slice data into "shards" or "splits" and distribute to workers
 - Compute set of intermediate key/value pairs
- Reduce: (interm_key, list(interm_value)) → list(out_value)
 reduce(interm_key, list(interm_val)):
 // DO WORK HERE
 emit(out_key, out_val)
 - Combines all intermediate values for a particular key
 - Produces a set of merged output values (usually just one)

MapReduce Word Count Example

Distribute

MapReduce Word Count Example

User-written Map function reads the document data and parses out the words. For each word, it writes the (key, value) pair of (word, 1). That is, the word is treated as the intermediate key and the associated value of 1 means that we saw the word once.

Map phase: (doc name, doc contents) → list(word, count)
 // "I do I learn" → [("I",1),("do",1),("I",1),("learn",1)]
 map(key, value):
 for each word w in value:
 emit(w, 1)

MapReduce Word Count Example

The intermediate data is then sorted by MapReduce by keys and the user's Reduce function is called for each unique key. In this case, Reduce is called with a list of a "1" for each occurrence of the word that was parsed from the document. The function adds them up to generate a total word count for that word.

Reduce phase: (word, list(counts)) → (word, count_sum)

```
// ("I", [1,1]) \rightarrow ("I",2)
```

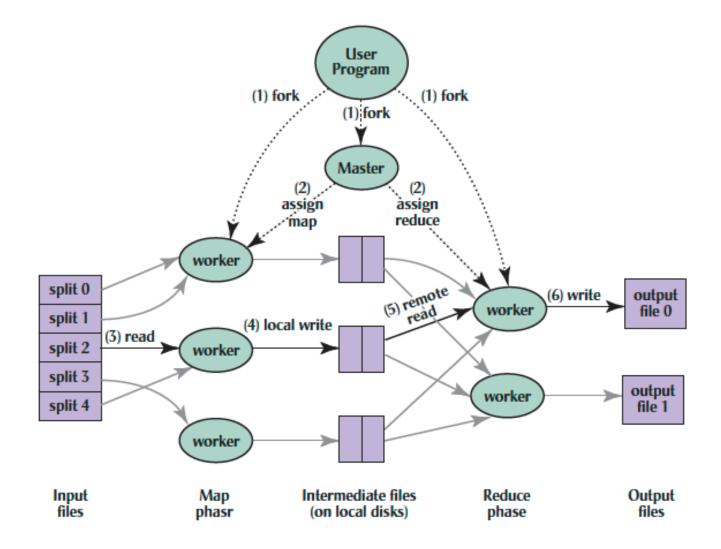

```
reduce(key, values):
  result = 0
  for each v in values:
    result += v
  emit(key, result)
```

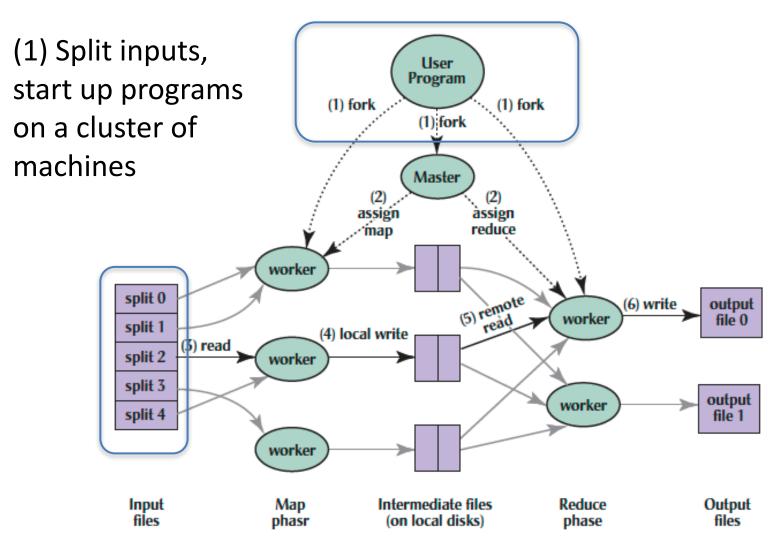

MapReduce Processing Example: Count Word Occurrences

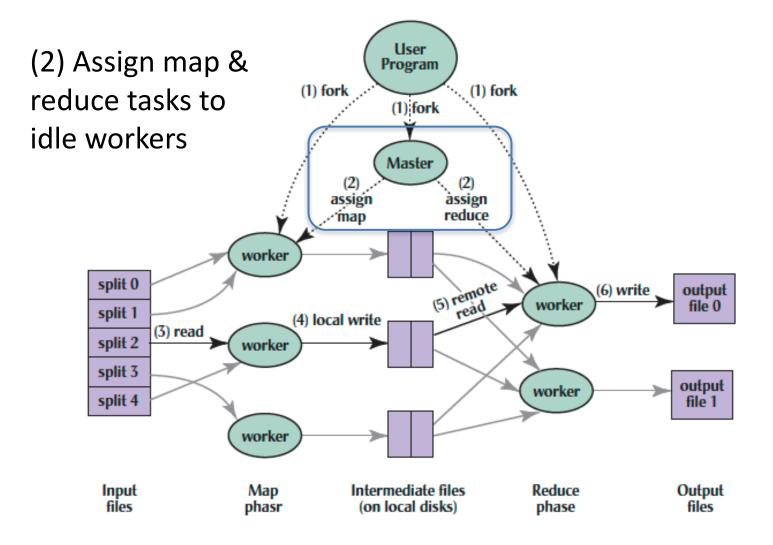

- Pseudo Code: for each word in input, generate <key=word, value=1>
- Reduce sums all counts emitted for a particular word across all mappers

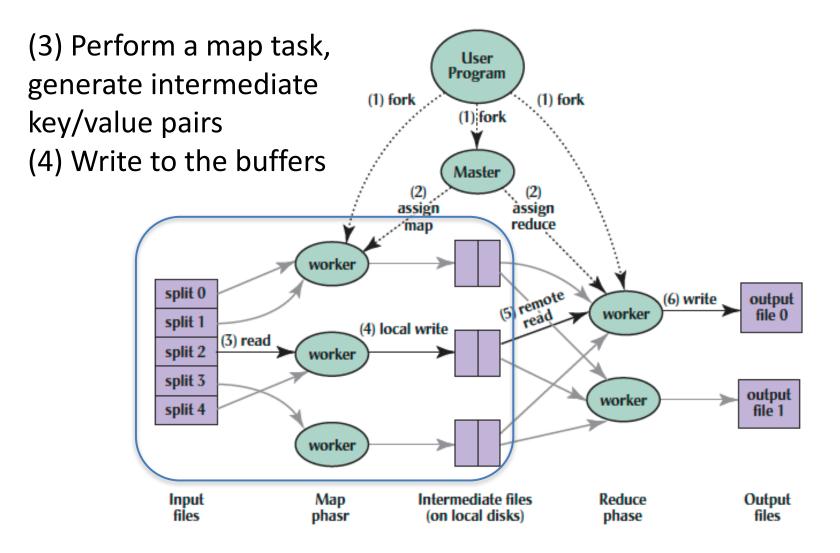

```
map(String input key, String input value):
    // input key: document name
    // input value: document contents
    for each word w in input value:
      EmitIntermediate(w, "1"); // Produce count of words
reduce(String output key, Iterator intermediate values):
    // output key: a word
    // intermediate values: a list of counts
    int result = 0;
    for each v in intermediate values:
      result += ParseInt(v); // get integer from key-value
    Emit(output key, result);
```

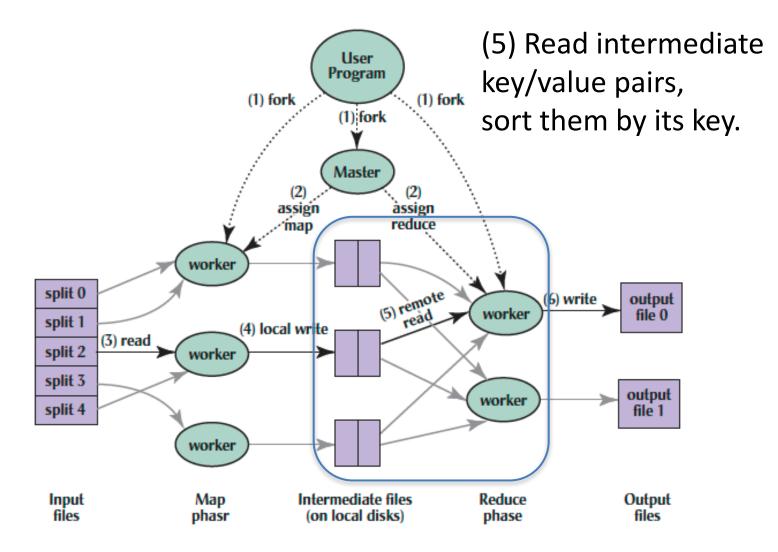

MapReduce Implementation

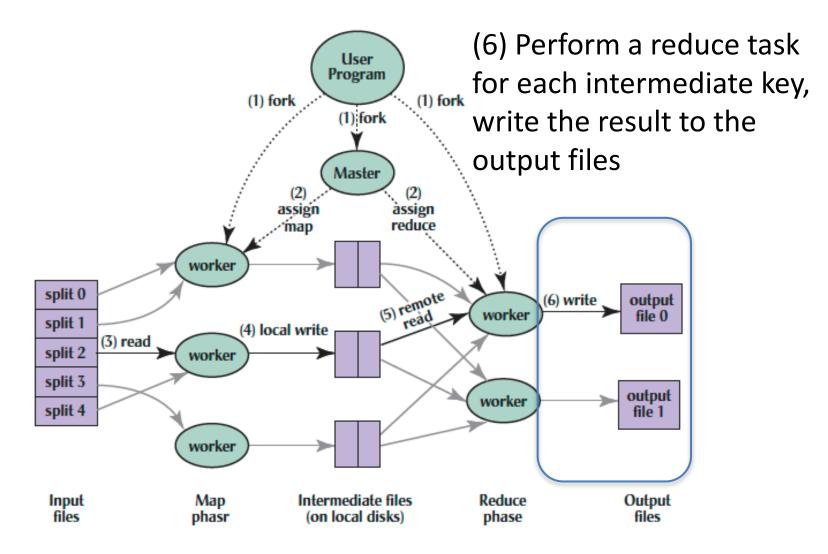

Big Data Framework: Hadoop & Spark

- Apache Hadoop
 - Open-source MapReduce Framework
 - Hadoop Distributed File System (HDFS)
 - Hadoop YARN Resource Management
 - MapReduce Java APIs
 - more than half of the Fortune 50 used Hadoop (2013)
- Apache Spark
 - Fast and general engine for large-scale data processing.
 - Running on HDFS
 - Provides Java, Scala, Python APIs for
 - Database
 - Machine learning
 - Graph algorithm

Word Count in Spark's Python API

// RDD: primary abstraction of a distributed
collection of items

- file = sc.textFile("hdfs://...")
- // Two kinds of operations:
- // Actions: RDD → Value
- // Transformations: $RDD \rightarrow RDD$
- // e.g. flatMap, Map, reduceByKey
- file.flatMap(lambda line: line.split())

.map(lambda word: (word, 1))

.reduceByKey(lambda a, b: a + b)

And, in Conclusion ...

- Warehouse-Scale Computers (WSCs)
 - New class of computers
 - Scalability, energy efficiency, high failure rate
- Cloud Computing
 - Benefits of WSC computing for third parties
 - "Elastic" pay as you go resource allocation
- Request-Level Parallelism
 - High request volume, each largely independent of other
 - Use replication for better request throughput, availability
- MapReduce Data Parallelism
 - Map: Divide large data set into pieces for independent parallel processing
 - Reduce: Combine and process intermediate results to obtain final result
 - Hadoop, Spark
